1. Introduction

Optical character recognition (OCR) systems have been widely used in recent years and various approaches are applied for developing their hardware and processing algorithms [1]. As for a small mobile OCR system, ex. a cognitive pen, usually an ideal model is thought as a system with high accuracy and speed, and minimum hardware size at the same time. Different movable OCR products are presently in the market [2] but they hardly ever afford the desired robustness and hardware size, simultaneously.

In this research we propose an associative memory based system for real-time character recognition and evaluate its performance with real data samples of English texts. The associative memory we use here as the main classifier is already designed in our lab [3] and has a mixed analog-digital fully-parallel architecture for nearest Hamming/Manhattan-distance search. The OCR system proposed here may be used ultimately in a cognitive pen product for online text recognition task.

2. Major System Steps

The major steps of the system are as shown in the block diagram of Fig. 1. It is worth-noting that all processes are achieved online.

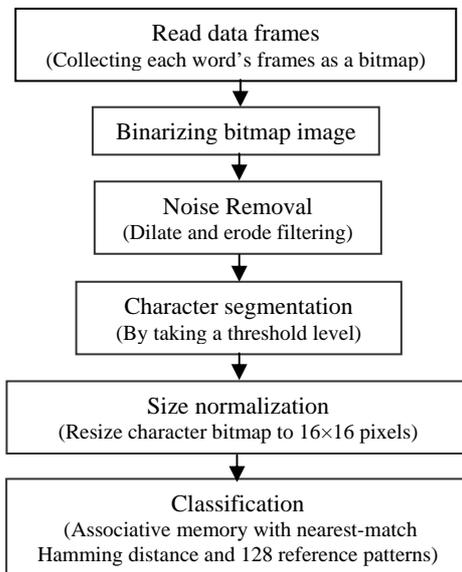

Fig. 1: Block diagram of major system steps.

For simplicity we suppose that at this phase the system is used only for recognition of printed texts. The first step is data reading where the reading device (scanner sensor) moves on each line of the text with an appropriate speed and scans the data continuously as a sequence of thin frames. The frames between each two word spaces are

collected and form a large frame as a gray-scale bitmap array which contains all the word characters. By taking a proper threshold value the image is binarized to a simple black-white bitmap (including noise). In order to remove noise from the frame, two different filters are applied for dilate and shrink of the image. Next, by employing a simple segmentation method and taking a threshold level the black segments within each frame are recognized and each one is considered as a single character.

To have an accurate classification each character size is normalized to 16×16 pixels before classification. We use a simple linear algorithm for resizing the character bitmap. The last and main step of the process is character classification which is carried out by a nearest-distance search algorithm applying the associative memory. The normalized segmented character is matched as a 256 bits vector to a number of reference patterns using the Hamming distance measure and the reference pattern with minimum distance is considered as the winner class. More explanations about the associative memory characteristics are given in Section 3.

3. Associative Memory Classifier

Figure 2 shows a simple architecture of the compact associative memory.

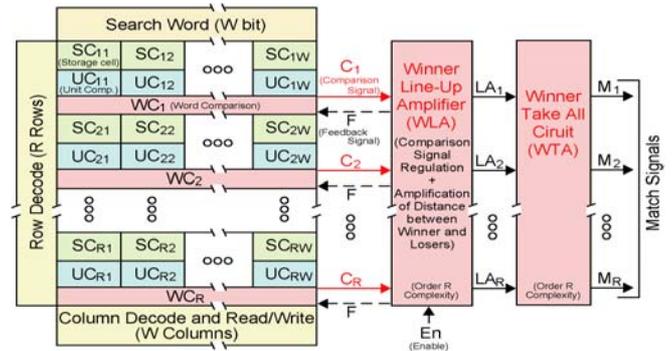

Fig. 2: Associative memory architecture.

A number of k-bit digital subtraction and absolute-value calculation units compare the W binaries in all rows of the memory field in parallel with the reference data. The WLA achieves a large regulation range for feedback stabilization and eliminates the inefficient possibilities of under- or over-regulation by a maximum-gain region which self-adapts to the winner input C_{win} . A signal follower provides the necessary high driving current for scaling to an increased number of reference patterns R. Low power dissipation of the system is achieved by an individual power regulation from the signal-regulation units for each input-signal source.

The transistor-count is only 6 per row. A modified version of the fast minimum circuit proposed by Opris et al. [4] is applied for combined feedback generation and distance amplification. The minimum function is used in the feedback loop and an intermediate node in each row circuit is used for the distance-amplified WLA-output LA_i . Table 1 shows the performance data of designed associative memory depending on the Hamming and Manhattan distance measure. More detailed information about the associative memory performance can be found in [3].

Table 1: Performance data of designed associative memory test chips.

| Distance Measure | Hamming | Manhattan (5 bit) |
|-------------------------------|------------------------|-------------------------|
| Memory Field | 32 x 768 | 128 x 80 |
| Technology | 0.6 μm CMOS | 0.35 μm CMOS |
| Area | 9.11 mm ² | 8.6 mm ² |
| Search Range | 0 - 400 bit | 0 - 480 bit |
| Winner-Search Time (Measured) | < 70 nsec | < 190 nsec |
| Performance | 1.34 TOPS | 160 GOPS |
| Power Dissipation | 43 mW | 91 mW |
| Supply Voltage | 3.3V | 3.3V |

4. Experimental Results

The system was simulated with a Matlab program. Different samples of scanned data including different fonts, noisy data, color background data, slightly rotated data, and data with different resolution were selected as the input samples. A total number of 80 samples for each character type were gathered. Figure 3 shows some data samples.

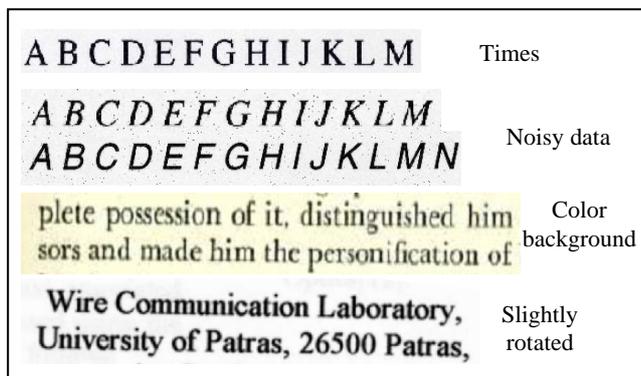

Fig. 3: Some text samples used as input data.

As mentioned in Section 2, each data sample is considered as a 256 bits vector. The experimental results of distance-matching between data vectors and reference patterns are reported in Table 2. As can be seen from the Table, excepting for the noisy data, the number of misclassified samples in other cases is zero. The minimum distance between winner and nearest-loser over all the data samples is 9 which is reliable enough. Figure 4(a) indicates the winner-input distance for different data samples. The average winner-input distance for all the input samples was calculated and found as 31 bits. Having this distance and referring to plot of Fig. 4(b) which gives the typical winner search time of the associative memory according to winner-input distance, we can find the average search time of 45 ns for classification of each test sample. This is the search time within 128 reference patterns and will be changed in case of increase in reference patterns number.

5. Conclusions

An associative memory based system for online character recognition is proposed in this paper. Taking an associative memory of 128 reference patterns size and 256 bits per pattern designed in 0.35 μm technology we could get an average nearest-search time of 45 ns for classification of different samples of characters written in Times and Arial fonts.

Table 2: Experimental results of data classification.

| Data type | Normal | | Noisy | | Color Background | | Slightly rotated | |
|--|--------|--------|--------|--------|------------------|--------|------------------|--------|
| | Times | Arial | Times | Arial | Times | Arial | Times | Arial |
| Font | Times | Arial | Times | Arial | Times | Arial | Times | Arial |
| Sample no. | 10 | 10 | 10 | 10 | 10 | 10 | 10 | 10 |
| Scan resolution | 70/100 | 70/100 | 70/100 | 70/100 | 70/100 | 70/100 | 70/100 | 70/100 |
| Misclassified samples | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 |
| Classified to different font (but still correct) | 1 | 1 | 1 | 0 | 2 | 0 | 2 | 1 |
| Min. distance of winner & nearest loser | 11 | 11 | 9 | 10 | 10 | 9 | 8 | 9 |
| Average distance of winner-input | 19 | 22 | 32 | 34 | 45 | 47 | 51 | 53 |

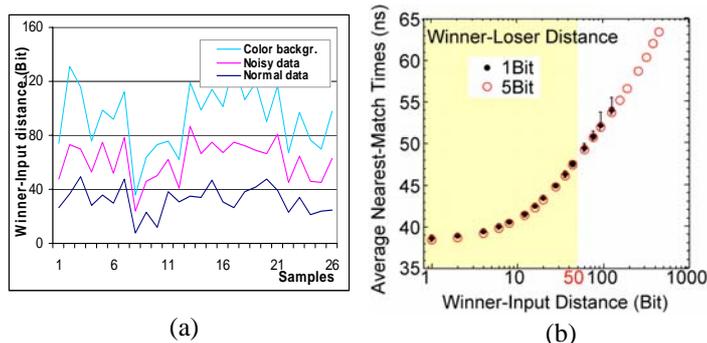

Fig. 4: (a) Winner-Input distance for different types of data. (b) Winner average search times in associative memory as a function of Winner-Input distance.

The initial classification results taken from real samples are acceptable however we still need to test the system with larger number of real data and also apply more effective algorithms for image preprocessing and noise removal. Comparing to OCR products existing in the market, however this prototype model is not yet robust enough but is advantageous in terms of classification time and hardware size. We are also planning to develop a system with a learning algorithm for optimizing the reference-pattern selection process.
